

Rezervoar je osnovni element svakog pogonskog agregata sa višestrukou ulogom: smeštaj radne tečnosti, odvođenje toplote, izdvajanje vazduha, taloženje nečistoće. Može poslužiti i za nošenje pogonskih i upravljačkih uređaja. Spada u grupu malih rezervoara a urađen je, odliven od lakog metala, sa rebrima za hlađenje i povećanje krutosti. Opremljen je nalivnim filtrom sa oduškom, pokazivačem max nivoa i čepom za ispuštanje ulja. Poklopac rezervoara je predviđen za skidanje radi obrade i montaže nosećih uređaja (pumpni agregat ili upravljački uređaj) a pričvršćen je vijcima.

Reservoir is basic element of hydraulic power unit. Although primarily functioning as a point of storage and supply for hydraulic system fluid, reservoir also assists in the separation of air and contaminants from the fluid and helps dissipate heat generated within the system. Frequently it is used as an integral part of the complete hydraulic power package, forming the base on which the el. motor/pump assembly, and associated valves are mounted. The reservoir is made of a light metal casting with ribs for better cooling and rigidity. It is provided with filling filter with breather, oil level gauge and drainage plug. A separate top cover fixed with bolts is foreseen to carry el. motor/pump assembly and control components.
